Pseudowire (PW) Management Information Base (MIB)

Abstract

This memo defines a Standards Track portion of the Management Information Base for use with network management protocols in the Internet community. In particular, it describes managed objects for modeling of Pseudowire Edge-to-Edge services carried over a general Packet Switched Network.

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it defines a MIB module that can be used to manage pseudowire (PW) services for transmission over a Packet Switched Network (PSN) [RFC3931] [RFC4447]. This MIB module provides generic management of PWs that is common to all types of PSN and PW services defined by the IETF PWE3 Working Group.

2. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB

module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

3. Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [BCP14].

This document adopts the definitions, acronyms, and mechanisms described in [RFC3985] and [RFC3916]. Unless otherwise stated, the mechanisms of [RFC3985] apply and will not be re-described here.

4. Overview

The PWE3 MIB modules architecture provides a layered modular model into which any supported emulated service can be connected to any supported PSN type. This specific MIB module provides the glue for mapping between the emulated service onto the native PSN service. As such, the defining of a PW emulated service requires the use of at least three types of MIB modules.

Starting from the emulated service, the first type is a service-specific module, which is dependent on the emulated signal type. These modules are defined in other documents.

The second type is this module, the PW-STD-MIB module, which configures general parameters of the PW that are common to all types of emulated services and PSN types.

The third type of module is a PSN-specific module. There is a different module for each type of PSN. These modules associate the PW with one or more "tunnels" that carry the service over the PSN. These modules are defined in other documents.

5. Structure of the MIB Module

The MIB module consists of six tables:

- The generic configuration and status monitoring objects that are common to all service types and PSN types (pwTable).
- The PW Performance Current Table (pwPerfCurrentTable) contains PW statistics for the current 15-minute period.

- The PW Performance Interval Table (pwPerfIntervalTable) contains PW statistics for historical intervals (usually 96 15-minute entries to cover a 24-hour period).
- The PW Performance 1-day Interval Table (pwPerf1DayIntervalTable) contains PW statistics for historical intervals accumulated per day. Usually 30 1-day entries to cover a monthly period.
- The mapping table (pwIndexMappingTable) enables the reverse mapping of the unique Pwid parameters [peer IP, PW type, and PW ID] and the pwIndex.
- The mapping table (pwGenFecIndexMappingTable) enables the reverse mapping of unique Pwid parameters used in genFecSignaling [pwGroupAttachmentID, pwLocalAttachmentID, and pwPeerAttachmentID] and the pwIndex.

This MIB module uses Textual Conventions from [RFC2578], [RFC2579], [RFC2580], [RFC2863], [RFC3411], [RFC3593], [RFC3705], [RFC4001], and [RFC5542], and references [RFC3413], [RFC4623], and [RFC4720].

6. PW-STD-MIB Module Usage

An entry in the PW table (pwTable) MUST exist for all PW types (ATM, FR, Ethernet, SONET, etc.). This table holds generic parameters related to the PW creation and monitoring.

A conceptual row can be created in the pwTable in one of the following ways:

- 1) The operator creates a row in the pwTable when configuring the node for a new service. This mode MUST be supported by the agent, and MUST be used when creating a non-signaled (manually assigned) PW.
- 2) The agent MAY create a row in the pwTable if a signaling message has been received from a peer node with signaling identification parameters that are not already known to the local node (i.e., there is no related entry created by the operator with matching parameters). This mode is OPTIONAL.
- 3) The agent MAY create a row in the pwTable automatically due to some auto-discovery application, or based on configuration that is done through non-SNMP applications. This mode is OPTIONAL.
 - The agent then creates the rows in the (locally supported) performance tables and reverse-mapping tables in PW-STD-MIB module.

7. Relations to Other PWE3 MIB Modules

- Based on the PSN type defined for the PW, a row is created in the PSN-specific module (for example, [RFC5602]) and associated to the PW table by the common pwIndex.
- Based on the PW type defined for the PW, a row is created in the service-specific module (for example, [CEPMIB]) and associated to the PW table by the common pwIndex.
- Unless all the necessary entries in the applicable tables have been created and all the parameters have been consistently configured in those tables, signaling cannot be performed from the local node, and the pwVcOperStatus should report 'notPresent'.

8. Relations to the IF-MIB

The PW in general is not an ifIndex [RFC2863] on its own, for agent scalability reasons. The PW is typically associated via the PWE3 MIB modules to an ifIndex the PW is emulating. This ifIndex may represent a physical entity -- for example, a PW emulating a SONET path as in Circuit Emulation Service over Packet (CEP). In that case, the PW itself is not an ifIndex; however, the PW-STD-CEP-MIB module associates the PW to the ifIndex of the path to be emulated. In some cases, the PW will be associated to an ifIndex representing a virtual interface. An example is Virtual Private LAN Service (VPLS) where the PW emulates a logical interface of a (logical) bridge. The physical ports' association to the VPLS instance is defined in the non-PW MIB modules in this case.

Exception to the above MAY exist in some implementations where it is convenient to manage the PW as an ifIndex in the ifTable. A special ifType to represent a PW virtual interface (246) will be used in the ifTable in this case.

When the PW is managed as an ifIndex, by default it SHOULD NOT be stacked, i.e., this ifIndex SHOULD NOT be layered above the respective PSN tunnel ifIndex or the attachment circuit ifIndex or the interface carrying the attachment circuit.

Note that the ifIndex that carries the PW toward/from the PSN is not explicitly configured via PWE3 MIB modules except in rare cases. In most cases, the PW is carried inside a PSN tunnel, and the interfaces carrying the tunnel are specified in the related MIB modules that control the PSN tunnels.

9. PW Notifications

This MIB module includes notifications for PW entering the up or down state, in accordance with the guidelines for interface notifications as described in [RFC2863]. Implementers should be aware that in many systems, it is desired to correlate notifications, such that notifications will not be emitted if notifications from a higher level (such as ports or tunnels) are already in effect. Specifically for PWs, it is anticipated that most network's equipment failures turn into lowerLayerDown state at the PW level, where a notification has already been emitted from a higher level.

When a PW is represented as an ifIndex, it is RECOMMENDED that PW notifications be turned off, to avoid duplication with the ifIndex status change notifications.

10. Example of the PW MIB Modules Usage

In this section, we provide an example of using the MIB objects described in section 7 to set up a CEP PW over Multiprotocol Label Switching (MPLS) PSN. While this example is not meant to illustrate every permutation of the MIB, it is intended as an aid to understanding some of the key concepts. It is meant to be read after going through the MIB itself.

In this example, a PW service for CEP is configured over an MPLS PSN (MPLS-TE tunnel). It uses LDP as in [RFC4447] for service setup.

For the operation in the service-specific MIB modules and the PSN-specific MIB modules, see the specific MIB module memo. This example is continued in the memo describing the PW-CEP-STD-MIB module (for example, [CEPMIB]) and the PW-MPLS-STD-MIB module [RFC5602].

In the PW-STD-MIB module:

In pwTable:

```

{
  pwIndex          5,

  pwType           cep,
  pwOwner          pwIdFecSignaling,
  pwPsnType        mpls,
  pwSetUpPriority  0, -- Highest
  pwHoldingPriority 0, -- Highest
  pwInboundMode    loose,

  pwPeerAddrType   ipv4,

  pwRemoteIfString "",
  pwRemoteCapabilities notYetKnown,
  ..
  pwOutboundVcLabel 0xFFFF, -- Will be received by
                                -- signaling protocol
  pwInboundVcLabel  0xFFFF, -- Will be set by signaling
                                -- protocol
  pwName             "Example of CEP PW",
  pwDescr            "",
  ..

  pwAdminStatus     up,
  ..
}

```

11. IANA PWE3 MIB Module

This section contains the initial version of the IANA-PWE3-MIB. IANA has updated this MIB module based on expert review as defined in [RFC5226]. Each new assignment of PW type or PW PSN type made by IANA based on the procedures described in [RFC4446] should be documented in the online version of IANA-PWE3-MIB. The current IANA-PWE3-MIB contains PW types as requested in [RFC4446] and [RFC4863].

DESCRIPTION

"This MIB module contains managed object definitions for pseudowire operation as in Bryant, S. and P. Pate, 'Pseudo Wire Emulation Edge-to-Edge (PWE3) Architecture' [RFC3985], Martini, L., et al, 'Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)' [RFC4447], and Townsley, M., et al, 'Layer Two Tunneling Protocol (Version 3)' [RFC3931].

This MIB module enables the use of any underlying packet switched network (PSN). MIB nodules that will support PW operations over specific PSN types are defined in separate memos.

The indexes for this MIB module are also used to index the PSN-specific tables and the PW-specific tables. The PW Type dictates which PW-specific MIB module to use.

STATUS current

DESCRIPTION

"A row in this table represents a pseudowire (PW) virtual connection across a packet network. It is indexed by pwIndex, which uniquely identifies a singular connection.

A row can be created by an operator command from a management plan of a PE, by signaling, or due to auto-discovery process. An operator's command can be issued via a non-SNMP application; in such case, a row will be created implicitly by the agent.

The read-create objects in this table are divided into three categories:

- 1) Objects that MUST NOT be changed after row activation. These are objects that define basic properties of the PW (for example type, destination, etc.).
- 2) Objects that MAY be changed when the PW is defined as not active. A change of these objects involves re-signaling of the PW or it might be traffic affecting. PW not active is defined as one of the following conditions:
 - a) The pwRowStatus is notInService(2).
 - b) The pwRowStatus is notReady(3).
 - c) The pwAdminStatus is down(2).

If the operator needs to change one of the values for an active row, the operator can either set the pwRowStatus to notInService(2) or set pwAdminStatus to down(2).

Signaling (or traffic) is initiated again upon setting the pwRowStatus to active(1) or setting the pwAdminStatus to up(1) or testing(3), respectively.

3) Objects that MAY be changed at any time.

A PW MAY have an entry in the ifTable in addition to the entry in this table. In this case, a special ifType for PW will be set in the ifTable, and the ifIndex in the ifTable of the PW will be set in the pwIfIndex object in this table.

By default, all the read-create objects MUST NOT be changed after row activation, unless specifically indicated in the individual object description.

Manual entries in this table SHOULD be preserved after a reboot; the agent MUST ensure the integrity of those entries. If the set of entries of a specific row are found to be inconsistent after reboot, the PW pwOperStatus MUST be declared as notPresent(5).

```

    other (5)
}
```

```
MAX-ACCESS read-create
```

```
STATUS current
```

```
DESCRIPTION
```

```
"This object is set by the operator to indicate the protocol
responsible for establishing this PW.
'manual' is used in all cases where no maintenance
protocol (PW signaling) is used to set up the PW, i.e.,
configuration of entries in the PW tables including
PW labels, etc., is done by setting the MIB fields manually.
'pwIdFecSignaling' is used in case of signaling with the
Pwid FEC element with LDP signaling.
'genFecSignaling' is used in case of LDP signaling with
the generalized FEC.
'l2tpControlProtocol' indicates the use of the L2TP
control protocol.
'other' is used for other types of signaling."

pwID OBJECT-TYPE

SYNTAX PwIDType
 MAX-ACCESS read-create
 STATUS current

DESCRIPTION

"Pseudowire identifier.

If the pwOwner object is 'pwIdFecSignaling' or 'l2tpControlProtocol', then this object is signaled in the outgoing PW ID field within the 'Virtual Circuit FEC Element'. For other values of pwOwner, this object is not signaled and it MAY be set to zero.

For implementations that support the pwIndexMappingTable, a non-zero value is RECOMMENDED, even if this identifier is not signaled. This is so that reverse mappings can be provided by pwIndexMappingTable and pwPeerMappingTable. It is therefore RECOMMENDED that the value of this pwID be unique (or if pwPeerAddrType is not 'unknown', at least [pwType, pwID, pwPeerAddrType, pwPeerAddr] is unique.)"

pwDown NOTIFICATION-TYPE

```
OBJECTS { pwOperStatus, --start of range
          pwOperStatus  --end of range
        }
```

STATUS current

DESCRIPTION

"This notification is generated when the pwOperStatus object for one or more contiguous entries in the pwTable are about to enter the down(2) or lowerLayerDown(6) state from any other state, except for transition from the notPresent(5) state. For the purpose of deciding when these notifications occur, the lowerLayerDown(6) state and the down(2) state are considered to be equivalent; i.e., there is no notification on transition from lowerLayerDown(6) into down(2), and there is a trap on transition from any other state except down(2) (and notPresent) into lowerLayerDown(6).

The included values of pwOperStatus MUST each be equal to down(2) or lowerLayerDown(6). The two instances of pwOperStatus in this notification indicate the range of indexes that are affected. Note that all the indexes of the two ends of the range can be derived from the instance identifiers of these two objects. For cases where a contiguous range of cross-connects have transitioned into the down(2) and lowerLayerDown(6) states at roughly the same time, the device SHOULD issue a single notification for each range of contiguous indexes in an effort to minimize the emission of a large number of notifications. If a notification has to be issued for just a single cross-connect entry, then the instance identifier (and values) of the two pwOperStatus objects MUST be identical."

DESCRIPTION

"This notification is generated when the pwOperStatus object for one or more contiguous entries in the pwTable are about to enter the up(1) state from some other state

except the notPresent(5) state and given that the pwDown notification been issued for these entries. The included values of pwOperStatus MUST both be set equal to this new state (i.e., up(1)). The two instances of pwOperStatus in this notification indicate the range of indexes that are affected. Note that all the indexes of the two ends of the range can be derived from the instance identifiers of these two objects. For cases where a contiguous range of cross-connects have transitioned into the up(1) state at roughly the same time, the device SHOULD issue a single notification for each range of contiguous indexes in an effort to minimize the emission of a large number of notifications. If a notification has to be issued for just a single cross-connect entry, then the instance identifier (and values) of the two pwOperStatus objects MUST be identical."

13. Security Considerations

It is clear that this MIB module is potentially useful for monitoring PW-capable PEs. This MIB module can also be used for configuration of certain objects, and anything that can be configured can be incorrectly configured, with potentially disastrous results.

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- o the pwTable contains objects to configure PW parameters on a Provider Edge (PE) device. Unauthorized access to objects in this table could result in disruption of traffic on the network. The objects pwUpDownNotifEnable and pwNotifRate control the reports from the network element to the EMS. Unauthorized access to these objects could result in disruption of configuration and status change reporting, resulting mis-view of the network conditions. The use of stronger mechanisms such as SNMPv3 security should be considered where possible. Specifically, SNMPv3 VACM and USM MUST be used with any v3 agent that implements this MIB module. Administrators should consider whether read access to these objects should be allowed, since read access may be undesirable under certain circumstances.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

- o the pwTable, pwPerfCurrentTable, pwPerfIntervalTable, pwPerf1DayIntervalTable, pwIndexMappingTable, pwPeerMappingTable, and pwGenFecIndexMappingTable collectively show the pseudowire connectivity topology and its performance characteristics. If an administrator does not want to reveal this information, then these tables should be considered sensitive/vulnerable.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

14. IANA Considerations

14.1. ifType for PW

IANA has assigned a value (246) for PW in the IANAifType-MIB called ifPwType.

14.2. PW MIB Modules OBJECT IDENTIFIER Values

A PW may appear as ifIndex in the ifTable, and therefore the pwStdMIB OBJECT IDENTIFIER has been assigned under the 'transmission' subtree, as the common practice in assigning OBJECT IDENTIFIERS for MIB modules representing entities in the ifTable.

All other MIB modules related to PW management SHOULD be assigned under the 'mib-2' subtree; individual requests will appear in the MIB module memo's IANA Considerations section.

14.3. IANA Considerations for PW-STD-MIB

The MIB module in this document uses the following IANA-assigned OBJECT IDENTIFIER values recorded in the SMI Numbers registry:

Descriptor -----	OBJECT IDENTIFIER value -----
pwStdMIB	{ transmission 246 }

14.4. IANA Considerations for IANA-PWE3-MIB

The MIB module in this document uses the following IANA-assigned OBJECT IDENTIFIER values recorded in the SMI Numbers registry:

Descriptor -----	OBJECT IDENTIFIER value -----
ianaPwe3MIB	{ mib-2 174 }

15. Acknowledgments

We thank Orly Nicklass for her dedicated review and significant edit in various sections of the document, and Kiran Koushik for his contribution.

The individuals listed below contributed significantly to this document:

Dave Danenberg - Litchfield Communications
Sharon Mantin - Corrigent Systems
